

Evaluator Report: Best Practices Grant, Lyme-Old Lyme, Connecticut

Archie C. Swindell, Ph.D., Quantitative Services

March 12, 2014

The Evaluation Approach

In general, evaluation of prevention programs begins with a strategic plan which identifies a target population and a set of specific objectives. The target population is defined by the region to be served and by the objectives. The objectives are selected from a list of prevalent issues, and are based on evaluation of the baseline conditions of the community, using surveys and public records.

Evaluation is based on both short-term (process) and long-term outcomes. Short-term evaluation tracks details of the processes, such as attendance at prevention-related training and functions, or the amount of media coverage. Records are entered regularly, under supervision of the coalition coordinator, into the official on-line database, from which they should be retrievable. Long-term outcomes are evaluated by surveying youth, parents and other adults, to determine practices and perceptions related to alcohol use. The surveys are conducted and reported upon by a coalition evaluator, usually an independent contractor. Outcomes are evaluated by analysis of trends within the target population, and by comparison with national and regional survey data, available on-line. The Youth Risk Behavior Surveillance (YRBS) survey [2, 3, 4, 5] is conducted in odd-numbered years in grades 9-12. YRBS results for 2013 have not yet been released. The Monitoring The Future survey (MTF) [6] is conducted every year in grades 8, 10, and 12.

Three primary risk factors were identified in the strategic plan issued in October, 2010 [1]: (1) easy access to alcohol, especially social access in homes; (2) low perception among youth of the risk of harm from regular consumption of alcohol; and (3) low enforcement of underage drinking laws. This report documents changes related to these risk factors, as well as the prevalence of alcohol consumption, both lifetime and current (any amount more than a sip in the 30 days prior to the survey). Lyme-Old Lyme data are derived from surveys of community youth and adults, conducted by Quantitative Services and Southeastern Conn. Regional Action Council.

Analysis of Trends

Results from four surveys in Lyme-Old Lyme public schools are tabulated, from the years 2006, 2009, 2011 and 2013. Current use (in the 30 days prior to the survey) and lifetime use of alcohol are presented, by grade and by gender (Tables 1, 2). Trends of decreasing use are apparent for both girls and boys. Linear regression analysis of prevalence vs. year reveals that the decreases are highly statistically significant ($p<0.001$). The largest decreases occurred between 2009 and 2011, following adoption of the coalition's strategic plan in 2010 [1], and implementation of prevention activities. Comparison of experience in Lyme-Old Lyme can be compared with national and Connecticut statistics, by gender and by grade, in Tables 3 and 4 (YRBS) and Table 5 (MTF). The YRBS data includes confidence

bounds, so it is possible to tell at a glance if a matching value from Lyme-Old Lyme is significantly different, within the 95% plus/minus probability interval.

Risk of harm from regular use of alcohol perceived by Lyme-Old Lyme youth is tabulated, also by grade and by gender (Table 5). Trends of increasing risk perception are apparent, and linear regression analysis confirmed the statistical significance ($p<0.001$). By 2013, girls perceived more risk than boys. Scores for increasing perceived risk are calculated using the formula footnoted in Table 5. For comparison, national figures for perceived “great harm” are available from the Monitoring The Future survey (Table 6).

Access to alcohol, another primary risk factor, was monitored by asking survey respondents who reported consuming alcohol at some time in their lifetimes to indicate how often they obtained alcoholic beverages from various sources. In Tables 7 and 8, prevalence of obtaining alcohol from home – with or without parental permission, and at parties – with or without adults present – are presented. Again, scores are calculated by formulas with the tables. Results are not reported when there were too few lifetime alcohol users to compute reliable statistics.

Enforcement of laws, the third risk factor, is not addressed directly in youth surveys. However, student awareness of school policies regarding consequences of drinking or possessing alcohol at school is monitored in the survey (Table 11). The calculated score for severity of consequences is somewhat higher in all grades in 2013 than in 2009. Without knowing what school enforcement policies actually are, this change should reflect either a change in policy or increased student awareness of policy.

The age of initiation of drinking alcohol is tabulated in two ways (Table 9). Lyme-Old Lyme is compared to national statistics (YRBS) in the percentage of all high school youth surveyed (grades 9-12) who started drinking before age 13. Figures in Lyme-Old Lyme have decreased since 2006, and are much lower than national averages. Also, the average ages when drinking first started are tabulated for grades 7-12, where there are enough lifetime drinkers to report reliably. Averages among older students increased between 2006 and 2009, and have remained stable since then. Postponement of starting to drink is a universal objective, because substance problems later in life are more likely if one starts young.

There is a strong association between drinking alcohol and using other substances (Table 10). Cigarette smoking has always been rare among non-drinkers (i.e., NO to 30-day use of alcohol), and has declined steadily among drinkers as well. For marijuana, except for 2011, marijuana 30-day use is reported by 30% or more of alcohol users, far more than by non-drinkers.

Data Limitations

The youth survey is given at about the same time biennially to a random sample of students, during a period or subject that is required of all students, to avoid environmental or selection bias. The sampling

variance is quite small, because most students present on the days of the survey are included. The racial and ethnic composition of the sample has been reasonably close to the whole district, according to the Strategic School Profile [7]. Youth surveys are screened for embedded quality-control criteria and for adequate information, and are omitted from analysis if they fail. As a result, about 5% of Lyme-Old Lyme surveys have been disqualified. In general, the consistency of responses between 2006 and 2009 – i.e. during the baseline period – is indicative of honesty in answering sensitive questions.
